1.2.1	Assessment of current status of fodder crop production and feed resources. Feeding calendar ...	7
	Kazakhstan	
1.2.2	Activity 4: Participatory evaluation and dissemination of improved fodder crops and agronomic packages to increase the feed resource base	7
	Kyrgyzstan	
1.2.3	Activity 4: Participatory evaluation and dissemination of improved fodder crops and agronomic packages to increase the feed resource base	8
1.2.4	Activity 5: Promoting efficient use of fodder crops, crop residues and agro-industrial by-products for increased meat and milk.....	10
	Tajikistan, Sogd province, Khujand site	
1.2.5	Activity 4: Participatory evaluation and dissemination of improved fodder crops and agronomic packages to increase the feed resource base	10
1.2.6	Activity 5: Promoting efficient use of fodder crops, crop residues and agro-industrial by-products for increased meat and milk.....	11
	Tajikistan, Vahdat district, Dushanbe site	
1.2.7	Activity 4: Participatory evaluation and distribution of improved fodder crops and agronomic packages to increase fodder resource base.....	11
1.3	Theme 3: Improvement livestock productivity	13
	Kazakhstan	
1.3.1	Activity 6: Early lambing for targeting lamb sale during Navruz (March) involving a genotype comparison in household flocks.....	13
1.3.2	Activity 7: Early weaning and fattening (Nagul) of lambs for lamb marketing and milking of early weaned ewes for value addition in household flocks.....	16
1.3.3	Activity 8: Community-based household cow and sheep milk processing improvement and sausage making for value addition and income increasing.	18
	Kyrgyzstan	
1.3.4	Activity 9: Improvement of livestock management for improved productivity: integrating management of lambing period, animal health, feeding system, lamb management	19
1.3.5	Activity 10: Production diversification: Improvement of milk productivity in sheep breeding.....	21
1.3.6	Activity 11: Set the basis for a decentralized and participatory breeding plan for farmers to access improved animals	23
1.3.7	Activity 12: Community-based household cow and sheep milk processing improvement for value addition and income increasing	25

	Tajikistan, Sogd province, Khujand site	
1.3.8	Activity 13: Improvement of goat breeding in households for improved productivity (flock structure, feeding, selection/culling and animal health)	25
1.3.9	Activity 14: Improvement of shearing and classification of fiber, standardization, based on the international standards, by quality, impurity and age.....	28
1.3.10	Activity 15: Set the basis for a decentralized and participatory breeding plan for farmers to access improved animals	30
1.3.11	Activity 16: Value added local processing of goat fibers by women and assessing the characteristics of naturally colored mohair and the potentials for its marketing	33
	Tajikistan, Vahdat district, Dushanbe site	
1.3.12	Activity 17: Improving sheep management in the communities, aspects of feeding, lamb breeding, maintaining and sheep reproduction.....	36
1.4	Theme 4: Knowledge exchange and capacity building	39
1.4.1	Activity 18: Enhancing knowledge exchange for increased feed and livestock production	39
2	Pakistan	40
2.1	Theme 1: Socioeconomics	40
2.1.1	Activity 1: Baseline Study of smallholder feed-livestock production systems at the rainfed and irrigated sites	40
2.1.2	Activity 1.2 Economic Evaluation of Feed-Livestock Production Technologies at the rainfed and irrigated sites	41
2.2	Theme 2: Forage Production	42
	Rainfed research site, Lodhay village	
2.2.1	Activity 2.1: Participatory on-farm evaluation and dissemination of winter cereal legume mixtures and technologies in crop – livestock systems	42
2.2.2	Activity 2.3: Development of green fodder selling enterprise using dug-well irrigation	45
	Irrigated research site, Sarghoda	
2.2.3	Activity 2: Comparison of yield and nutritional value of improved winter and summer fodder crops and varieties with local fodder crops; seed production; preservation/conservation of fodder crops through hay and silage making and cultivation of multi-cut hybrids, Mott grass and multiple planting of maize crops for lean periods.	45
2.3	Theme 3: Livestock Productivity	52
	Rainfed research site, Lodhay village	
2.3.1	Activity 3: Evaluation of effect of feeding improved fodder crop varieties and concentrates on milk yield and quality in buffalos and cows and on meat production	52
2.3.2	Activity 4: Adding value to livestock products through preservation and processing of milk	53
	Irrigated research site, Sarghoda	
2.3.3	Activity 3: Evaluation of effect of feeding different fodder crop varieties (green fodder and hay/silage) and concentrates on milk yield and quality in buffalos & cows and on meat production in buffalo and cow calves	55
2.3.4	Activity 4: Adding value to livestock products through preservation and processing of milk	57
2.4	Theme 4: Knowledge exchange	58
2.4.1	Activity 5: Enhancing knowledge exchange for increased feed and livestock production	58
3	Regional Activities	59
3.1	Activity 1: Regional (across site) analysis for Theme 1 “Socioeconomics” in Central Asia	59
3.2	Activity 2: Capacity building: training of scientists in the area of integrated feed resources and livestock production at ICARDA and in the countries.....	59
3.3	Activity 3: Capacity building: English training of scientists to improve the international scientific exchange	60
3.4	Activity 4: Project supervision and interregional knowledge exchange: regional workshops and SCM.....	60
3.5	Activity 5: Web based knowledge exchange (Virtual information Center).....	60
III	Problems during the reporting period and steps taken to remedy these problems	61
IV	Progress expected during the following reporting period.....	61

I Introduction

This report covers the period from 1 January to 31 December 2008 and relates to the last twelve months in the second annual workplan.

The second annual workplan specified detailed activities for each region, each research theme and country/project site. The section on project implementation and achievements (II) in this progress report is organized accordingly by region, themes and countries. Regional activities are reported in a separate section. The present report is based on progress reports by the national teams that were received in January and March 2008.

For Theme 1 in Central Asia the present report briefly describes the progress in the planned activities; all technical results will be summarized in an updated version of the first socioeconomic report from April 2008. The updated report is in preparation by Aden Aw-Hassan and Nariman Nishanov. For Theme 2 and Theme 3 in Central Asia and for all activities in Pakistan some preliminary results will be presented to illustrate the progress and achievements of the activities. However, the statistical analysis and most of the cost benefit evaluations will be done when the activities have been completed (mostly in autumn 2009).

In addition to the this annual progress report two detailed progress/technical reports were prepared: 1) on activity 16 "Value added local processing of goat fibres" by Liba Brent (University of Madison, Wisconsin) in March 2008 and March 2009 describing the results from the field missions to Khojand/Tajikistan in April/May and October/November 2008; and 2) on the breeding activities (activities 10, 11 and 15) by Joaquin Mueller in November 2008 after his field mission to Kyrgyzstan, Tajikistan and ICARDA HQ in October/November 2008. All technical reports were shared with IFAD.

An additional important source of information on the progress and achievements of the project is the IFAD supervision mission report prepared by Antonio Rota which gives an excellent overview of the state of project activities

The major activities in 2008 included:

- Conduction of the producers' survey in Central Asia (CA)
- Continuation of market studies of sheep and goat products and value chain analysis in CA
- Socioeconomic evaluation of technologies in Pakistan and initiation of economic evaluation in CA
- Continuation of field experiments under Themes 2 and 3 (activities 4-17) in CA
- Second cultivation cycle of summer crops and third cultivation cycle of winter crops (testing of improved varieties and agronomic measures) in Pakistan
- Feeding experiments with cattle and buffalos testing the new fodder crops and balanced rations in Pakistan
- Inclusion of Master and PhD students into the project activities in CA and Pakistan
- Updating of the project webpage and training of webmasters in the partner institutes in CA
- IFAD supervision mission in Kyrgyzstan, Tajikistan and Pakistan in April 2008
- Second annual national workshops in four countries in October 2008
- Inter-regional workshop and second SCM in Dushanbe/Tajikistan from 24-27 November 2009, including field visits to the project sites near Khojand and Dushanbe.

II Project Implementation and Achievements

1 Central Asia

1.1 Theme 1: Socioeconomics

Kazakhstan

1.1.1 Activity 1: Livestock producers’ survey

Sampling frame and procedure

- The sampling frame was developed from January to March 2008 using a clear geographical territory and farm household typologies
- Sampling procedure was defined, and sample was selected;
- List of 3 villages and 150 households to be interviewed were identified
- Preliminary analyses of the collected data included:
 - o characteristics of households
 - o households’ land assets
 - o livestock flock size of smallholders
 - o marketing practices of households.

In the previous technical report marketing practices are not discussed in detail, this will be done in the next technical report.

Developing of production and market survey

Household questionnaire was adapted and tested for local conditions by May 2008

Training of enumerators and researchers

Enumerators and researchers were trained by May 2008

Enumerators	Institution	Date of training	Place of training
2 researchers	South-West Research Center of Livestock and Crop Science, Int’l Kazakh-Turkish University	18 March 2008	South-West Research Center of Livestock and Crop Science in Shymkent
2 MSc students	Int’l Kazakh-Turkish University		
3 students	South Kazakhstan State University		

Conducting of multi-theme survey of livestock keepers in the target area and data entry.

- Survey was conducted from June to August 2008
- Data were entered into database in August-September 2008.

1.1.2 Activity 2: Assessment of economic feasibility of the newly introduced technologies

Results obtained by September 2008:

1. Cost benefit analysis of the early lambing technology was completed. However, the methodology should be reviewed.
2. Cost benefit analysis of fattening of the early weaned lambs was completed. Results show that this technology helps to increase the profit from sales of each lamb by 75%.
3. A rough estimate of the cost benefit ratio for cow and sheep milk processing was done. The data indicate that milk processing for production of cheese (called chechel) does not generate enough income to cover milk and labor costs and to achieve a significant profit:

Technology	Milk (l)	Price per liter of milk (Kaz. Tenge)*	Total cost of milk (Kaz. Tenge)	Produced cheese (kg)	Price per kg of cheese (Kaz. Tenge)
Chechel production	10	50	500	1	1200
Income	700 KZT				

*1 USD= 120 Kaz. Tenge (KZT)

1.1.3 Activity 3: Analysis of livestock market integration

The questionnaire for weekly livestock price data collection was elaborated and tested by May 2008

Price data collection was conducted at two rural (Arys and Badam) and two urban (Turkistan and Shymkent) livestock markets from June to December 2008. It is expected to be completed by June 2009. So far analysis of traded livestock by the volume of transactions and animal types has been conducted for the period May-August 2008. Supply of lambs at all livestock markets significantly increased from July. For example, at Shymkent livestock market, the quantity of sheep in May was 1,100 sheep, while in July it reached 2,000 sheep. This trend, similar to both Kyrgyzstan and Tajikistan, indicates that smallholders anticipate a cold winter and try to sell more lambs rather than buy expensive forage for winter. Lamb prices decreased in July and slightly increased in August due to the wedding season.

Kyrgyzstan

1.1.4 Activity 1: Livestock producers' survey

Sampling frame and procedure

- The sampling frame was developed from January to March 2008 using a clear geographical territory and farm household typologies.
- Sampling procedure was defined, and sample was selected;
- List of 3 villages and 150 households to be interviewed were identified

Developing of production and market survey

Household questionnaire adapted and tested for local conditions by May 2008.

Training of enumerators and researchers

Training of enumerators and researchers was conducted in March 2008 at the Agrarian University in Bishkek.

Enumerators	Institution	Date of training	Place of training
3 researchers	Kyrgyz Agrarian University, Kyrgyz State University	28 March 2008	Kyrgyz Agrarian University in Bishkek
6 students	Kyrgyz Agrarian University		

Conducting of multi-theme survey of livestock keepers in the target area and data entry.

- Survey was conducted from June to August 2008
- Data were entered into database in August-September 2008
- Preliminary analyses of the collected data included:
 - o characteristics of households
 - o major income sources
 - o income generated from the livestock production with special emphasis on small ruminants
 - o marketing practices of households.

1.1.5 Activity 2: Analysis of livestock market integration

The questionnaire for weekly livestock price data collection was elaborated and tested by May 2008.

Price data collection was conducted at three livestock markets, one in Tokmok town and two in Bishkek, from June to December 2008. It is expected to be completed by June 2009. So far analysis of traded livestock by the volume of transactions and animal types has been conducted for the period June-Sept. 2008. Regular fuel price increase pushed lamb prices up in the beginning of the year. This was followed by a massive supply of lambs from rangelands in late July that pulled prices down. This increase in supply was also caused by a very dry season and, consequently, lack of forage on the summer ranges.

1.1.6 Activity 3: Analysis of price dynamics for livestock products, feed / forage, and staple food

Price data were collected for January to December 2008, and factors of price change were determined for all three types of commodities by December 2008. Nominal food prices have increased by 20-25% from January to December 2008. For the same period, feed prices increase was recorded in August, but by the end of 2008 they went down to the January level. The maximum lamb meat price was recorded in July 2008; by the end of the year prices decreased by 5-10% compared to the level recorded in January.

Tajikistan, Sogd province, Khujand site

1.1.7 Activity 1: Mohair goat producers' survey

Sampling frame and procedure

- The sampling frame was developed by January 2008 using a clear geographical territory and farm household typologies.
- Sampling procedure was defined, and sample was selected.
- List of 5 villages and 150 households to be interviewed were identified.
- Small ruminant populations were obtained.

Developing of production and market survey

Household questionnaire adapted and tested for local conditions by May 2008.

Training of enumerators and researchers

Enumerators and researchers were trained in March 2008 (see above comments).

Enumerators	Institution	Date of training	Place of training
2 researchers	Tajik Research Institute of Livestock	17 March 2008	Tajik University of Technology
5 students	Agrotechnology department, Tajik University of Technology		

Conducting of multi-theme survey of livestock keepers in the target area and data entry

- Survey was conducted from June to August 2008
- Data were entered into database in August-September 2008.

1.1.8 Activity 2: Mohair traders' survey

Identification of the target markets for survey

Mohair markets were selected by March 2008.

Developing of mohair market survey

Traders' questionnaire adapted and tested for local conditions by May 2008

Train enumerators and researchers

Enumerators and researchers were trained by May 2008.

Conducting of survey of mohair traders in the target area and data entry.

- 50 traders were interviewed by November 2008. The survey is expected to be completed by March 2009 rather than end of 2008, as many traders are expected to return from Russia to Tajikistan in winter.
- Data entry will be finalized by April 2009

1.1.9 Activity 3: Analysis of price dynamics for livestock products, feed/forage, and staple food

Price data were collected for the period from January to December 2008, and factors of price change were determined for all three types of commodities by December 2008. There was no significant change on mohair market. Demand from the foreign buyers remains weak, and mohair as well as yarn prices have not changed in spite of the price hike for staple food and feed/forage recorded in the first half of 2008. Price data for staple food and feed indicate that there was a decrease of these prices that started in September 2008 and continued till December. However, food and feed prices still remain higher than those recorded at the end of 2007.

Tajikistan, Vahdat district, Dushanbe site

1.1.10 Activity 1: Livestock producers' survey

Sampling frame and procedure

- Sampling frame was developed from January to March 2008 using a clear geographical territory and farm household typologies.
- Sampling procedure was defined, and sample was selected.
- List of 11 villages and 150 households to be interviewed were identified.

Developing of production and market survey

Household questionnaire adapted and tested for local conditions by May 2008.

Training of enumerators and researchers

Enumerators and researchers were trained in March 2008.

Enumerators	Institution	Date of training	Place of training
3 researchers	Tajik Research Institute of Livestock	14 March 2008	Tajik Research Institute of Livestock in Dushanbe, Karsang village in Vakhdat district
3 temporary workers hired for survey	Local administration office in Vakhdat district		

Conducting of multi-theme survey of livestock keepers in the target area and data entry.

- Survey was conducted from June to August 2008

- Data were entered into database in August-September 2008.

1.1.11 Activity 2: Analysis of livestock market integration

The questionnaire for weekly livestock price data collection was elaborated and tested by May 2008.

Price data collection was conducted at two urban (Sharora and Chorbogh) and two rural (Sangob and Eski Bozor) livestock markets from June to December 2008. It is expected to be completed by June 2009. Preliminary results show that the highest number of livestock is sold at Rudaki market located nearby Dushanbe city limits. From June to August lamb prices have been increasing. Major factors explaining the price movement in June are the rising feed/forage prices and 30% fuel price hike recorded in 2008 from May to September. In July, despite increased supply of lambs brought for sales from the summer ranges, demand caused by the wedding season pushed lamb prices higher.

In general, better marketing conditions exist in Rudaki and Sharora livestock markets. Most of the livestock producers were concerned about the winter season and try to sell as many sheep as possible to avoid high forage costs. The other reasons for early sales of lambs are the peak condition of lambs and lack of forage on rangelands due to exceptionally dry season. This definitely will negatively affect the size of households' flocks and limit the reproduction opportunities for the next year.

1.1.12 Activity 3: Analysis of price dynamics for livestock products, feed / forage, and staple food

Price data were collected for the period from January to September 2008, and factors of price change were determined for all three types of commodities by December 2008. Data show that beef and lamb meat prices increased for 9 months of 2008 by 20 and 29%, respectively, while live lamb prices gained about 40% for the same period.

1.2 Theme 2: Range and Forage Productivity

1.2.1 Assessment of current status of fodder crop production and feed resources. Feeding calendar

A questionnaire for a comprehensive survey on feeding strategies and forage production was developed and distributed to the partners in the three countries by the end of September 2007. The aim of the questionnaire was to interview about thirty farms and households in each village including those participating in the project and neighboring households.

Data collection for comprehensive survey finalized in May 2008 in three villages at each research site (total 314 respondents): 75 in Dushanbe; 90 in Khujand; 75 in Kyrgyzstan; 74 in Kazakhstan. The most common and popular forage crops planted by households and farmers of the selected villages are maize and alfalfa. The yields of planted forage crops are often low. Forage production becomes an economic disadvantage for the households when livestock prices are low and labor, machinery, and fuel costs are high and increasing. Therefore, farmers need higher yielding varieties of forage crops. In addition, the length of the grazing season and the efficiency of grazing management will be optimized with the available forage crops.

The majority of the respondents were interested in cultivation of forage crops such as sorghum, millet and forage beet. Sorghum and proso millet can be successfully grown in households and farmer's field in the Khujand site, Tajikistan, as grain for animal feeding and for seed multiplication of improved varieties.

The preliminary results from the feed survey also point at the need for improved grazing management. This need is enforced by the prevailing scenario of increasing fuel prices and decreasing area under fodder crops, salinization of irrigated lands, drought and heat problems, and low priority to fodder production. Overstocking of rangelands nearby settlements can decrease available feed resources in the region. It seems that the shortage of feeds and fodders will be a great challenge to the future livestock production in the project sites' villages.

Kazakhstan

1.2.2 Activity 4: Participatory evaluation and dissemination of improved fodder crops and agronomic packages to increase the feed resource base

Activity 4.1: Community action for improving the carrying capacity of degraded rangelands around settlements

Activity 4.1.1 Effect of oversowing on productivity of degraded rangeland

The experiment could not be carried out due to a severe cold in the winter 2007/2008 and flooding in spring 2008 followed by a drought. The flood in the South Kazakhstan province was caused by heavy rains and the melting of snow due to a sudden rise in the temperature in March 2008. The rangeland and agricultural land in Akdala village were completely flooded. Thus, the planting of the experiment had to be postponed and Haloxylon and Kochia were planted in December 2008 according to approved workplan.

4.1.2. Effect of continuous and rotational grazing on productivity of natural pastures

Natural pastures are an important feed resource for livestock production. Therefore, research approach to develop improved system of the pasture management is the most important issue. It is essential to develop this system as animals are grazed in the steppes almost around year.

It is known that diverse plant composition effects to the grazing system differently: at continuous grazing the pastures can be degraded while in proper pasture rotation can increase productivity of the livestock and ranges, and also it improves forage crops composition in the pasture.

It is necessary to note that many communities have certain practices and knowledge on grazing animals in their respective pastures; however, they are not experienced yet to manage pasture rotation on pastures nearby village.

Therefore investigations of this activity are linked to introduce improved pasture rotations on the basis of plant composition by seasons of the year.

The grazing experiment testing rotational grazing was started in May 2007 and all planned measurements on biomass and botanical composition were carried out. However, the grazing was not

managed by the herder according to the agreed experimental plan. Several times the researchers discussed with the farmer to assure grazing of sheep according to the experimental scheme. As this failed, it was decided to discontinue the experiments. However, it is being discussed to analyze and present the data collected on seasonal changes in biomass quantity and quality.

Activity 4.2: On-farm demonstration of improved fodder production options

Three experiments were conducted.

Experiment 1

Improved maize hybrid from Uzbekistan was brought and planted at two households' fields on four different planting dates according to the approved workplan for 2008. The objectives of this study were to study the impact of different planting dates on maize performance under irrigated conditions. The experiment was completely randomized with four replications. Four planting dates were tested, 15 April, 30 April, 15 May and 30 May 2009. The results showed that the sowing date on 30 April gave the highest average biomass (12.6 t) and grain yields (6.8 t) in both farms but the yields did not differ significantly from sowing on 15 May (11.7 and 6.3 t).

Experiment 2

Two maize seeding rates (25 and 35 kg/ha) were evaluated on two farms in Akdala village. First year results showed that the higher seed rate increased the average biomass yield by 0.57 t and the grain yield by 0.36 t.

Experiment 3

Traditionally no fertilizer is applied to alfalfa (*Medicago sativa*) under irrigation in Kazakhstan in the first harvest year. The aim of this experiment was to study effect of ammophous fertilizer on alfalfa biomass in the first harvest year. Three treatments were tested: control with no fertilizer application; 40 kg/ha ammophous; and 60 kg/ha ammophous. Four cuts were done during the vegetation period. The overall yield of green fodder mass was equal to 20.7 t per hectare in the control, 21.2 and 23.4 t per hectare with 40 and 60 kg/ha ammophous application, respectively.

Kyrgyzstan

1.2.3 Activity 4: Participatory evaluation and dissemination of improved fodder crops and agronomic packages to increase the feed resource base

Assessment of botanical composition and biomass

Dry conditions in the last three years in Kyrgyzstan led to a decrease in productivity of natural hayfields. In 2008 the dry biomass yield of the natural hayfield yield was 420 kg/ha composed of 185 kg/ha annual grass (44.0 %), 5 kg/ha legumes (1.2 %), 32 kg/ha sedges (7.6 %), 90 kg/ha wormwood (21.4%), and 72 kg/ha forbs (17.1 %). Wormwood is consumed by animals when the plant is dry.

4.1. Effect of over-sowing and ammonium nitrate fertilization on productivity of hayfields

Three experiments were conducted.

Experiment 1

The effect of two tillage methods for over-sowing with sainfoin (*Onobrychis viciifolia*) on productivity of hayfields was studied in the natural hayfield of Aymseit farm, namely plowing and minimal tillage (disking) and compared to the natural hayfield. Over-sowing with sainfoin and tillage methods (full and minimum tillage) increased the productivity of the natural hayfield from 397 kg/ha to 661 kg/ha, with diskings and 787 kg/ha with plowing.

Experiment 2

There are several forms of nitrogen available for fertilization of spring hayfields, but ammonium nitrate is the most common type in Kyrgyzstan. Ammonium nitrate can be used any time during the vegetation because surface volatilization losses are minimal. In this experiment, ammonium nitrate

was applied at the rate of 50 kg/ha, and the natural hayfield was used as control. The results of the experiment showed that, ammonium nitrate application led to 13 % higher plant cover and increased plant height by 7 cm larger but plant germination percentage was 16 % lower than in the control.

Experiment 3

Oversowing a natural hayfield with two different seeding rates of sainfoin (50 and 70 kg/ha) with disking as land preparation were compared with an undisturbed natural hayfield as control. Plant density, plant height and biomass yield were determined.

The analysis shows that the natural hayfield (control) produced a higher dry biomass (419 kg/ha) than the two treatments oversown with sainfoin. The lower yield can be explained by the fact that sainfoin grows slowly in the year of establishment and that about 30-40% of the natural grasses were damaged by disking and planting with the seeder. It is expected that the yield in the two treatments will increase in the second harvest year. The higher seeding rate of 70 kg/ha led to higher plant density and higher biomass than the rate of 50 kg/ha (Table 1).

Table 1. Effect of two seeding rates on the productivity of natural hayfields oversown with sainfoin

Treatments	Plant density (no/ m ²)	Plant height (cm)	Yield (kg/ha)
1. Control (natural hayfield)	19.0	24.25	418.8
2. Disking + sainfoin 50 kg/ha	61.2	12.75	345.5
3. Disking + sainfoin 70 kg/ha	89.5	12.75	406.0
	LSD ₀₅ 2.7	LSD ₀₅ 0.8	LSD ₀₅ 18.6

Activity 4.3: Integration of food/feed legumes into cereal cropping systems

Wheat, barley and maize continued to be the major crops grown by private and public sectors in Kyrgyzstan. It is proposed to introduce mung bean or pearl millet into the continuous wheat and barley cropping practiced by the households at the project site to increase good quality forage and to improve soil fertility. Nevertheless, it will be difficult to change Government policy that tends to concentrate on one or two agricultural crops. In this case, crop diversification can be reached only through cultivation of alternative crops in the marginal or degraded lands.

Experiment 1

In the reporting period, mung bean seeds were purchased from the Southern part of Kyrgyzstan where they are widely grown, while they are not common in Chuy province. Fields continuously planted with wheat or barley were selected on three farms and divided into two. One half was planted according to common practice with cereals, the other half was planted with cereal followed by mung bean. Preliminary results showed that a seeding rate of 20 kg mung bean per hectare was optimal under the conditions of Chuy province. The experiment will be repeated in 2009 and results presented for two consecutive years.

Experiment 2

It is well known that drought tolerant varieties of pearl millet have a great potential for agriculture in drought-affected regions. Three varieties of pearl millet were obtained from ICARDA and planted at the central experimental station of the Kyrgyz Research Institute of Veterinary, Livestock and Pastures and in the backyard of one of the scientists. Pearl millet had not been planted before in Kyrgyzstan. That is why the experiment was done mainly at the research station.

Biomass and grain yields were determined and compared with maize. The highest biomass yield was obtained from HHVBC tall 36.9 and 35.3 at the research station and in Joldosh household. This was higher than the maize yield with 32.3 and 30.8 t/ha but not significantly different from variety EEBC, while the biomass yield of the third variety Raj 171 only amounted to 25 and 26.5 t/ha at the research

station and in Joldosh household. The highest grain yields (1165 and 1092 kg/ha) were obtained from the variety EEBC in both research sites; the other varieties did not differ much from each other or from maize.

1.2.4 Activity 5: Promoting efficient use of fodder crops, crop residues and agro-industrial by-products for increased meat and milk

Experiment 1

A feeding experiment was conducted in Alimseyit farm in Kemin district over a period of two months to compare the feeding of chopped and unchopped types of coarse fodder. The experiment showed that the quantity of residues after feeding was reduced through chopping with the exception of sainfoin hay which was consumed equally well in both forms (Table 2).

Table 2. Percent of forage type eaten

	Forage type				
	Alfalfa hay	Natural hay	Barley straw	Sainfoin hay	Barley (grain)
Control	70	62	48	90	100
Experimental group	95	89	78	88	100

The experimental group of sheep was fed by a diet of chopped fodder and agricultural by-products. The results of the experiment showed higher weight gain in the group receiving chopped feed during the fattening period compared to the control but the difference was not significant (Table 3).

Table 3. Live weights and weight gains during the fattening period (average per head)

Treatments	Liveweight (kg)		Growth rate	
	15/01/2008 r	15/03/2008r	Total (kg)	Daily growth rate (g)
Control	32.9 ± 1.8	39.3 ± 3.7	6.4	107
Experimental group	32.5 ± 1.3	42.8 ± 2.3	10.3	171

Experiment 2

A second feeding experiment with the same objective was carried out in two households in Akbeket village with 13 adult sheep each. The control group (Toktogunov Erkin) was fed with unchopped straw and the experimental group (Rysbekov Shaken) with chopped straw. The experiment showed that the loss in the liveweights of the sheep over the winter period was decreased in the experimental group (12.8 kg) compared to the control group (16.6 kg).

Tajikistan, Sogd province, Khujand site

1.2.5 Activity 4: Participatory evaluation and dissemination of improved fodder crops and agronomic packages to increase the feed resource base

Activity 4.1: Community action on improving productivity of degraded pastures close to the villages

Two experiments testing the effect of nitrogen application and of reseeding with saltwort and Persian clover were conducted in the selected rangeland site. The meteorological data in 2008 showed that the temperatures were very low in January and February 2008 and that there was a drought in spring (high temperature and low rainfall). The total precipitation was only 23 mm during the whole vegetation period according to the meteorological station called Aeroport).

Experiment 1

The experiment was started on 5 April 2008 when some rain was received. 50 kg/ha nitrogen was applied by hand in the natural rangeland according to the experimental design. Field observations of growth and development were made during the vegetation period from 5 April to 25 August 2008. However, due to the drought biomass production was very low and no effect could be measured. The same experiment is being repeated in 2009.

Experiment 2

Planting of saltwort, Persian clover and of the mixture was done in March, later than originally planned due to the cold winter. Nitrogen was applied at the rate of 40 kg/ha. The lack of rain led to a poor germination and poor plant growth. In the beginning of June the percentage of germinated seeds was as follows: 28.6% for saltwort, 11.1% for Persian clover, and 16.6/5.3 % for the mix of saltwort/Persian clover. Later on the plants died because of the continued water shortage.

Activity 4.2.1 Introducing nontraditional crops into existing crop rotation

Crop diversification has started in Northern Tajikistan. Nevertheless wheat, barley, and maize continue to be the major agricultural crops grown by the private and public sectors in the country. The project proposes to introduce nontraditional crops such as pearl millet and sorghum into the existing crop production system in the households. Maize, pearl millet, and sorghum were planted after winter wheat harvest in the beginning of June. Yield was recorded before harvest. The research results show that with irrigation of 700-800 m³/ha and fertilizer dressing at the rate of 150 kg/ha is sufficient to get good yields from maize, pearl millet, and sorghum even during a dry year. Seed emergence was higher in pearl millet (78 %) than in sorghum (67%) and maize (66 %). Plant density of sorghum (290 plants per m²) was higher than that of maize (200) and pearl millet (199), while plant height as well as the number of leaves per plant of maize was higher than pearl millet and sorghum.

1.2.6 Activity 5: Promoting efficient use of fodder crops, crop residues and agro-industrial by-products for increased meat and milk

Low-quality cereal crop residues, especially rice straw, are important feed resources in the smallholder crop-livestock systems. It was planned to test new feeding rations from January to March 2008 including the use of a locally made chopper for chopping straw and other crop residues. Due to the cold winter and related scarcity of feeds this activity had to be postponed to the next winter season (December 2008 to February 2009).

Tajikistan, Vahdat district, Dushanbe site

1.2.7 Activity 4: Participatory evaluation and distribution of improved fodder crops and agronomic packages to increase fodder resource base.

Activity 4.1: Improving carrying capacity of degraded rangelands and hay pastures and effect of nitrogen fertilization on productivity of hayfields

Two experiments were conducted with two households to rehabilitate natural hayfields through surface application of nitrogen-phosphorus fertilizer and planting of sainfoin. The natural hayfields are currently dominated by *Hordeum bulbosum*.

Experiment 1

Oversowing the natural hayfield with 60 kg/ha sainfoin was compared with a seeding rate of 80 kg/ha and with a natural hayfield. The average biomass yield at the end of the vegetation period was 0.74 t/ha for the seeding rate of 60 kg/ha sainfoin and 0.79 t/ha for a rate of 80 kg/ha, while the biomass of the natural hayfield (control) amounted to 2 t/ha. This experiment is being continued in 2009. It is expected that the biomass and nutritional quality produced on the improved hayfield will increase considerably in the second and coming years.

Experiment 2

Fertilizers (ammonium nitrate and ammophos) were applied by hand according to experimental design. Field observations and data collection were carried out according to the workplan. The results showed that plant height of the *Hordeum bulbosum* in the stage of flowering was 150-160 cm with nitrogen application, and 110-120 cm in the control, while plant height of wild oat *Avena trichophora* was 70-80 cm with nitrogen application and in the control 25-35 cm. The same trend was observed in dry biomass yield. The average dry biomass yield with nitrogen and phosphorous application *Hordeum bulbosum* was increased 2.2 times compared to the control. The results indicate that the productivity of hayfields in the highlands of Tajikistan could be increased considerably by application of nitrogen and ammophos fertilizers.

Activity 4.3: Integration of legumes into cereal cropping systems

The area of rangelands around the village is limited, the plant cover is highly degraded, and yield is low due to overgrazing. A considerable part of forage has to be produced on the irrigated croplands. The farmers in Vakhdat district cultivate vegetables and cereal crops (wheat and rice). They grow alfalfa for hay and maize for grain and fodder. Presently farmers increase the area of forage crops, especially alfalfa, as forages have a good market potential. Furthermore, after continuous cultivation of cereals (in particular wheat) the soil fertility has decreased, and farmers are searching for options to increase soil fertility in the irrigated land. However, the yield of fodder crops on irrigated and rainfed fields is low due to lack of knowledge of best agronomic practices for growing fodder.

Experiment 1

It was assumed that early maturing varieties of food-feed legumes would be more suitable for double cropping after the wheat harvest. However, the comparison of an early and a late maturing variety of mung bean showed little difference in grain yields between the two tested varieties and the two households. The comparison of produced biomass was non-conclusive: in one household the early maturing variety produced more than the late maturing one, while it was the opposite in the other household. However, the experiment clearly showed that households can obtain good grain and fodder yields from planting mung bean as a summer crop.

Experiment 2

In the second Tajik-2 was sown after harvesting wheat at two seeding rates (15 and 20 kg/ha). Planting was done by hand method. Growth characteristics and yields did not differ much between the two seeding rates. Two households were involved to the experiment.

Experiment 3

Alfalfa (*Medicago sativa*) has been in use for a long time in Central Asia. The crop is mainly cultivated under irrigated conditions in Tajikistan. In the first harvest year alfalfa usually produce low biomass yields as the root system is not yet well developed. Traditionally alfalfa is not fertilized in the first year. In this experiment alfalfa was fertilized in the first year with 40 kg/ha and 60 kg/ha ammophos and compared to a control without fertilizer. The first cut was done on 27 April at the beginning of flowering with a height of 75-80 cm. The plants were cut manually at a height of 5-7 cm from the ground. In total alfalfa was cut 5 times during the vegetation period (spring-summer-autumn), and the overall fresh biomass yield was 22.6 t/ha, 23.5 and 20.7 t/ha in the control, and with 40 and 60 kg/ha ammophos application, respectively; the corresponding dry biomass yields were 5.4, 5.8 and 4.9 t/ha, respectively. Thus, applying 40 kg/ha ammophos proved to increase the biomass yield in the first yield but it is probably not economically feasible.

1.3 Theme 3: Improvement livestock productivity

Kazakhstan

1.3.1 Activity 6: Early lambing for targeting lamb sale during Navruz (March) involving a genotype comparison in household flocks

Location: Ak-Dala village (Arys district)

Objective:

The main objective is to test impact of early lambing on performance of ewes and lambs and on farm economics

Activities and results:

In the households "Abdukarim", "Andas", "Ergesh", and the farm "Kasymbay" Karakul and fat-tailed ewes were divided into two groups: experimental group, in which sheep were mated in August and control (traditional), in which ewes were mated in October 2007 (Table 4). Accordingly the lambing of experimental group occurred in December 2007, and of the control group in March 2008. The framers were also trained on additional feeding of sires during mating and feeding of ewes during gestation.

Table 4. Experimental Design (number of ewes mated/inseminated in 2007)

Households	Karakul sheep		Fat-tailed sheep	
	early	traditional	early	traditional
Farm "Kasimbay"	43	57	48	52
Household "Abdukarim K."			17	23
Household "Ergesh"	4	6	8	12
Household "Andas"	9	11	6	4

Lambing rate was in most cases as high in the group with early lambing as in the group traditional lambing; prolificacy was in some cases even higher in the early lambing group (Tables 5-8).

High lamb mortality was observed in the early lambing group of Karakul lambs in households "Andas" (67%) and "Ergesh"(75%). However, both households also experienced relatively high moratlity (67%) in Karakul lambs born in the traditional group. Relatively low mortality was observed among fat-tailed lambs with early lambing in households Kasymbay (25.5%) and Abdukarim (15.8%). There were several reasons for the high mortality of lambs: 1. Severe and prolonged winter, snow from end of November and until March, at the end of winter a lot of rain and still frost, which caused flood and destruction of houses and farm buildings in Akdala. 2. Lack of preparation of households Andas and Ergesh for the severe and prolonged winter (insufficient storage of fodders and lack of shelters). 3. Small number of ewes in the experiment, in household Ergesh 4 lambs only in the early lambing group (Karakul), so each death changes the rate drastically. As a result of the difficult natural conditions and the high mortality occurred the households Andas and Ergesh refused to further participate in the project activities.

Table 5. Prolificacy of ewes and lambs survival rate at farm "Kasymbay"

Parameters	Early lambing		Traditional lambing	
	Karakul	Fat-tailed	Karakul	Fat-tailed
Ewes inseminated (heads)	43	48	57	52
Ewes lambed (heads)	41	45	57	52

Lambs survived/remaining at weaning (heads)	-	5 (71.4%)	3 (33.3%)	9 (75.0%)

The dynamics of lambs in the traditional group showed slightly higher liveweights than the live weight with early and traditional lambing from lambing to 2.5 monthly age showed that there are not significant differences in live weight between lambs of early and traditional lambing.

Table 9. The dynamics of live weight of lambs in the early lambing group

Households	Breed	Live weight of lambs, kg					
		3 days	15 days	1 month	1.5 month	2 months	2.5 months
Abdykarim	Fat-tailed	4.1	6.1	12.0	17.6	21.5	35.4
Kasymbay	Karakul	3.5	5.3	8.6	12.6	13.2	19.9

Kasymbay	Karakul	3.5	5.2	8.7	13.2	15.8	22.4	24.8	26.1	28.2	31.4
	Fat-tailed	3.9	5.7	10.9	16.4	22.7	34.9	36.5	38.8	41.1	42.3

Table 11. Economical comparison of early and traditional lambing

Parameters	Kasymbay				Abdukarim	
	Early		Traditional		Early	Traditional
	Karakul	Fat-tailed	Karakul	Fat-tailed	Fat-tailed	
Expenses for maintaining 1 sheep (Tenge)	2232	2232	2952	2952	3168	4152
Average selling price of 1 lamb at Navruz (Tenge)	2879	5060	-	-	5460	-
Live weight of lambs at Navruz (kg)	19.9	32.9	-	-	35.4	-
Price for 1 kg liveweight (Tenge)	144	153.8	-	-	154.2	-
Income at Navruz (Tenge)	647	2828	-	-	2292	-
Average selling price of 1 lamb in August (Tenge)	5000	10500	3497	8719	-	9678
Live weight of lambs in August (kg)	35.4	47.2	31.4	42.3	-	43.7
Price for 1 kg liveweight (Tenge)	141.2	222.4	111.4	206.1	-	221.4
Income in August (Tenge)	2768	8268	545	5767	-	5526

The comparison of market prices for lambs shows that there was no advantage in selling lambs at Navruz based on price per kg of liveweight; actually the price of fat tailed sheep was higher in August. The early lambing intervention was discussed with farmers in a training workshop. It was clarified that this method can only be successfully applied with appropriate feeding and shelter during the winter lambing. The farm Kasymbay achieved higher income when selling lambs from early lambing in August than from traditional lambing. However, selling early lambing lambs during Navruz was less profitable than selling traditional lambs in August for Kasymbay and for the household Abdukarim. The

farmers see the main advantage from selling at Navruz in obtaining cash income in March, when there are no other sources of income.

The experiment is being repeated in 2008/2009 in Ak-Dala village with Kasymbay and Abdukarim and two new households in Akbulak village, Ordabasin district located 27 km from Shymkent. The number of ewes per household, sheep breed and treatment is between 14-25 ewes (Table 12).

Table 12. Experiment design for 2008/2009 (number of ewes mated/inseminated in 2007)

Participating farms/households	Karakul		Fat-tailed	
	early	traditional	early	traditional
Farm Kasymbay	20	25	20	25
Household Abdukarim	-	-	15	20
Household Bahytjan	-	-	15	17
Household Abish	-	-	14	15

1.3.2 Activity 7: Early weaning and fattening (Nagul) of lambs for lamb marketing and milking of early weaned ewes for value addition in household flocks

Location: Ak-Dala village (Arys district)

Objectives:

The main objective is to test impact of early weaning on performance of lambs and milk production of ewes as well as the effect on the farmers' income.

Activities and results:

The ewes on the farms Kasymbay and Abdukarim were inseminated artificially (Table 13). To increase the conception rate artificial insemination was done during two cycles. After completion of the second cycle rams were admitted for 20 days to the ewes to cover ewes that had not conceived through AI. In the experimental group weaning was done 75 days after lambing and in the traditional groups at 4 month age.

Table 13. Experimental Design (number of ewes inseminated in October 2007)

Households	Karakul sheep		Fat-tailed sheep	
	early	traditional	early	traditional
Kasymbay	50	63	54	50
Abdukharim	-	-	24	20

All ewes in both groups lambed. While a higher mortality of both Karakul and fat-tailed lambs was observed for early weaning than for the traditional system in the farm Kasimbay, early weaned lambs showed a lower mortality in the household Abdukarim (Table 14).

Table 14. Prolificacy of ewes and lambs' survival rate at the farm Kasymbay and in the household Abdukarim

Parameters	Farm Kasimbay				Household Abdukarim	
	Karakul		Fat-tailed		Fat-tailed	
	early	traditional	early	traditional	early	traditional
Ewes inseminated	50	63	54	50	21	23
Ewes lambed	50	63	54	50	21	23
Conception rate (%)	100	100	100	100	100	100
Lambs obtained	50	63	54	50	21	23

Lambs died (heads)	9 (18.0%)	6 (10.5%)	10 (18.5%)	2 (4.0%)	2 (9.5%)	3 (13.0%)
Lambs remained for experiments	41	57	44	48	19	20

The daily ration of ewes consisted of 2.5 kg hay, 0.25 kg chopped barley and 0.25 kg chopped corn; the ewes were fed twice per day.

At weaning (75 days after lambing) the ewes in the early weaned group were around 2-3 kg heavier than the ewes in the traditional group (Table 15). The highest difference between the groups was observed five months after lambing, thereafter the difference decreased to 0.5-1.3 kg seven months after lambing.

Table 15. Dynamics of liveweights of ewes

Liveweights	Farm Kasimbay				Household Abdukarim	
	Karakul		Fat-tailed		Fat-tailed	
	Early	traditional	Early	traditional	Early	traditional
At lambing	35.7	35.6	41.6	40.7	43.8	43.3
30 days	40.1	40.5	44.2	44.3	50.0	49.8
60 days	45.4	44.7	49.4	47.2	52.3	52.0
75 days	50.1	47.1	52.0	49.8	55.8	53.7
90 days	52.7	50.1	53.4	51.1	58.3	55.3
120 days	54.3	51.0	56.2	54.1	64.5	58.7
150 days	57.6	53.4	59.5	57.3	67.4	60.6
180 days	58.5	57.7	63.6	61.5	68.3	64.5
210 days	60.0	59.5	63.8	62.5	67.8	66.2

The liveweight of the lambs in the early weaned groups was smaller at early weaning (45 days) than in the traditional group and this was still the case at weaning of the traditional group (4 months). When the lambs were sold with seven months the early weaned lambs were slightly heavier (Table 16). The fat-tailed lambs were more than 10 kg heavier than the Karakul lambs. The price per lamb differed only slightly between the early and traditionally weaned lambs.

Table 16. Dynamics of liveweights of lambs

Liveweights	Kasimbay				Abdukarim	
	Karakul		Fat-tailed		Fat-tailed	
	Early	Traditional	Early	Traditional	Early	Traditional
At lambing	4.0	4.0	4.0	4.0	4.2	4.1
30 days	10.1	10.1	10.2	10.3	12.9	13.0
60 days	14.1	16.0	16.7	22.8	22.4	22.5
75 days	15.7	16.6	18.0	23.9	24.7	24.8
90 days	17.3	18.9	19.4	25.7	25.1	27.8
120 days	20.4	21.7	23.0	28.8	28.7	31.3
150 days	27.3	28.6	34.4	37.8	35.7	38.6
180 days	33.9	34.2	41.5	45.0	43.7	46.6
210 days	37.9	35.9	47.5	45.8	49.9	47.7

Milk production was only measured in the farm Kasymbay and only with 10 ewes per breed and group. During two months daily milk yield was measured every five days once per day in Karakul and fat-tailed ewes in the early and traditional weaning groups (Table 17). The average milk yield for the two month period ranged from 400 to 590 g per day and was higher in the early weaned ewes; fat tailed ewes gave on average 60 g more milk per day than Karakul ewes.

Table 17. Karakul and fat-tailed ewes' milk productivity be periods of lactation, gram/day Dynamics of liveweights of lambs

1.3.3 Activity 8: Community-based household cow and sheep milk processing improvement and sausage making for value addition and income increasing.

Location: Ak-Dala village (Arys district)

Activities and results:

Following tasks were conducted during 2008:

- further improvements of technologies for production of chechil, homemade cheese, brynza and homemade sausage;
- preparing of chechil and training of farmers (January);
- preparing of rennet and training of farmers (March, April);
- preparing of homemade cheese and training of farmers (May, June);
- preparing of kurut with cherry and training of farmers (July, August);
- preparing homemade sausage and training of farmers (September, October);
- preparing of brynza and training of farmers (November, December)

Processing methods for milk products that are demanded on the market were developed and applied in the household Elan (G. Kuleeva) and at Kasimbay farm. In the training chechil preparation technology on 17 January 2008 25 households from Akdala village and A. Ombaev, B. Narbota, E. Kunanbaeva, and A. Saniyazova from the South West Research Institute participated. During the training some of the householders learnt of the. About 15 households decided to process milk in the future and 4 of them are already producing chechil.

As differences in composition of cow's milk may require changes in the preparation or cause differences in the flavor of milk products, the composition of cow's milk was analyzed four times during the year at the times when feeding and climate change most drastically. Protein content in the milk produced in autumn exceeded spring and summer milk by 0.15 and 0.23%; fat percent was also highest in autumn (Table 18).

Table 18. Seasonal composition of cow’s milk

	Chemical composition of cow's milk (%)				
	Winter	Spring	Summer	Autumn	Average
Protein	3.05	3.00	2.92	3.15	3.03
Fat	3.65	3.63	3.65	3.78	3.68

1.3.4 Activity 9: Improvement of livestock management for improved productivity: integrating management of lambing period, animal health, feeding system, lamb management

Location: Kemin district – Alimseyit farm and 10 households in Akbeket village

Objectives:

The main objective is to improve farmers’ and households’ knowledge of livestock management in small and medium scale farms through implementation of improved husbandry practices.

Activities:

Improved husbandry practices were implemented in the medium scale farm “Alimseyit” (Kemin district) and in 10 households located in the “Akbeket” village of Kemin district.

The improved husbandry practices include:

- Optimum grazing on the pastures around the village with additional feeding in late autumn, winter and early spring periods;
- Supplemental feeding in winter;
- preparation sheds for animals (mechanical cleaning, disinfection);
- Monitoring of sheep lambing;
- Monitoring of growth and development of lambs;
- periodical observation and examination of animals,
- Training of farmers and households for diagnoses and prophylactics of sheep diseases
 - o vaccination of sheep against clostridiosis
 - o Trenching (anthelmintics) against intestinal parasites;
 - o bathing against itching.

The training was conducted jointly for the farm Alimseyit, the households from Akbeket, Kenesh farm and the households Progress community. The training theme was “Veterinary and sanitary measures for improving health and growth of lambs, including preventive measures against brucellosis”. The workshop participants were informed about feeding during gestation and lactation and requirements for sheds for adult and young animals. They were trained in methods of disease treatment, and in preventive measures against infectious diseases with special attention to brucellosis. Training materials were distributed to the farmers and households.

The winter 2007/2008 was exceptionally cold with relatively little snow (compared to the last 40 years). In Bishkek during 2 months temperatures remained at about -30°C. In addition the summer 2008 was very dry, posing extra challenges to the workplans.

Results in Akbeket community:

The 10 households Akbeket applying the improved management scheme were encouraged to collaborate more closely, in particular in the joint use of the remote pastures in summer, and in marketing. In autumn and winter 2007 the sheep were grazed on pastures around village and fed twice a day by a mixture of hay and straw. During the lambing period sheep were fed with concentrates following the recommendations of the scientists. A subgroup of five out of the 10 households is also participating in the improved breeding scheme (see below). In 2007/2008 data have been collected from the 10 “improved” flocks and from 2 “traditional” flocks to assess the effect of improved management on flock productivity. In order to enable a more reliable comparison the number of traditional farmers in Akbeket village was increased to five farmers in autumn 2008, namely T. Duysheev with 27 ewes, T. Moldaliev with 10 ewes, T. Ibraimov with 32 ewes, M. Jumabekov with

12 ewes, and K. Aydaraliev with 20 ewes. The data collection and analysis is ongoing and the results will be presented in the final report. To provide conclusive results will not be easy as intensity of data collection and the level of adopting recommended practices differ between the three groups of households (“improved management and breeding”, “improved management” and “traditional management”).

Preliminary results from improved management at Alimseyit farm and from comparing fine-wool and coarse wool sheep production:

To improve the wool quality in fine wool sheep, 8 Orgochor sires were bought in 2007 and a selection scheme implemented for ewes that started with culling non-qualifying ewes in 2007.

The fine and coarse wool sheep of Alimseyit farm were kept separately on the Jelargy winter pasture in 2007/2008. During late gestation and lambing the ewes received the feed ration shown in Table 19. Coarse and fine wool lambs born in 2008 were treated against intestinal helminths by albendazolum, the adult sheep were bathed against mange in spring and all flocks were sent off to the distant summer pastures. Because of the drought it was decided to conduct the mating season in 2008 one month earlier: the coarse wool sheep were mated in September and the fine wool sheep in October.

Table 19. Daily feed rations for ewes at Alimseyit

Name	Amount per head (kg)	Starch Units	Digestible protein (g)	Calcium (mg)	Phosphorou s (mg)	Caroten e (mg)
Recommended	-	1.25	120	-	-	-
Alfalfa hay	0.5	0.24	42.5	6.2	0.7	25
Mountain hay	0.5	0.25	25.0	3.6	0.5	20
Straw	0.5	0.15	5.0	1.5	0.3	2
Barley	0.3	0.36	28.5	0.3	1.0	-
Total	1.8	1.00	101	-	-	-

At lambing in spring 2008 there were 150 coarse wool ewes and 216 fine-wool ewes of different ages (from 2 to 7 years old, Tables 20 and 21). Lambing of coarse wool sheep began on 16 February and ended on 20 March 2008; lambing of fine wool sheep began on 5 April and ended on 2 May 2008. Out of 135 born, six coarse wool lambs died: 2 because of the bezoar disease, and 4 because of carelessness. Out of 226 lambs born, 19 fine wool lambs died: 7 heads because of the bezoar disease, 2 from white-muscle disease and 10 because of carelessness.

Table 20. Liveweight and mortality of ewes at mating in 2007 and lambing in 2008

Breed	No of ewes at start of mating	Average liveweight in autumn	No of ewes at the start of lambing	Average liveweight after lambing	Ewes died	
					Heads	%
Coarse wool sheep	160	47.1	150	40.6	10	6.25
Fine wool	230	42.7	216	38.4	14	6.08

Table 21. Reproductive parameters of the fine and coarse wool flocks in the lambing season 2008

Breed	Ewes aborted		Barren ewes		Twins		Lambs survived	
	heads	%	heads	%	heads	%	heads	%
Coarse wool sheep	7	4.7	14	9.4	10	6.7	129	86.3
Fine wool	7	3.2	13	6.0	20	9.3	207	96.0

The comparison of wool quantity and quality in 2007 and 2008 shows an improvement in quantity but not in quality (Table 22).

Table 22. Quantity and quality of fine wool (averages from 2007 and 2008) in Alimseyit farm

Year	% output	Fineness of wool (μ m)	Natural length of wool (cm)	Average wool yield (kg)	Wool produced (kg)
2007	53.31	21.59	7.70	3.01	875
2008	54.61	21.82	7.80	3.30	1098

There is also an indication of improved lamb liveweights in the fine wool sheep from 2007 to 2008, while there is nearly no difference in liveweights of the coarse wool lambs between the two years (Table 23).

Table 23. Average liveweights of lambs in 2007 and 2008

Years	Breed	At lambing (kg)	At 15 days age (kg)	At weaning (kg)
2007	Fine wool	3.0	5.9	28.5
2008		3.5	6.6	29.2
Difference		0.5	0.7	0.7
2007	Coarse wool	4.2	7.4	31.5
2008		4.3	7.5	31.7
Difference		0.1	0.1	0.2

While coarse wool was sold for 5 Som per kg in both years, the price of fine wool doubled from 40 som per kg in 2007 to 80 Som in 2008. The increase in quantity per head and the high price increase led to a much higher income from fine wool in 2008 compared to 2007 (Table 24).

Table 24. Wool yields and income obtained in 2007 and 2008

Breed	Group	Wool yield			
		2007		2008	
		kg/head	Total, kg	kg/head	Total, kg
Fine wool	Sires	4.74	38	6.08	48
	Ewes	2.96	473	3.51	758
	Young females	2.68	187	2.12	154
	Castrates	3.40	177	3.85	138
Average		3.01	-	3.30	-
Total		-	875	-	1098
Total (Krg som)		-	35000	-	87840
Coarse wool	Sires	1.92	25	2.19	13
	Ewes	1.54	140	2.20	330
	Young females	1.19	70	1.30	45
	Castrates	1.67	61	1.75	50
Average		1.35	-	1.99	-
Total		-	296	-	438
Total (Krg som)		-	1480	-	2190

In order to ensure a full comparison between fine wool and coarse wool sheep, the income from lambs has to be assessed.

1.3.5 Activity 10: Production diversification: Improvement of milk productivity in sheep breeding

Location: Chuy district – Kenesh farm and household in Progress village

All activities related to breeding are being supervised by Joaquin Mueller from INTA, who visited Kyrgyzstan and Khojand from 25 October to 16 November 2008 and prepare a detailed report on activities 10, 11 and 15 that was shared with IFAD in March 2009).

Activities in Kenesh farm and in Progress village:

Table 25 gives an overview of the planned and conducted activities (please compare detailed report from Mueller).

Table 25. Overview on planned and performed activities (composed by Mueller, 2008)

Date	Planned Activity	Performed Activity
Oct 2007	New Awassi rams from Kazakhstan are introduced into the nucleus.	Two new Awassi rams were bought.
Oct 2007	Participants in Progress village agree on Awassi rams to be used in their flocks.	Four farmers agreed on the use of one old purebred Awassi ram of the nucleus.
Oct 2007	Participants select appropriate ewes for mating with Awassi rams.	Farmers selected appropriate ewes for mating.
Nov 2007	Mating in nucleus and participating flocks	Mating started 15 November
Apr 2008	Lambing. F1 Awassi lambs are identified and ear tagged.	Progeny in nucleus flock and Awassi progeny in farmer flocks were identified and ear tagged.
May 2008	Milking starts in the nucleus.	Milking in the nucleus started June 15 and milk recording was performed every 10 days on 10 Awassi graded ewes and 10 control (F1) ewes.
May 2008	An initial training in milk processing is planned at this time to be held in Tokmok (Muhi El Dine, from ICARDA, in following already standard plans in this regard)	Training was done at the nucleus farm on June 14 2008 using regional expertise.
Oct 2008	A new cycle of mating with Awassi rams takes place with further ewes included in the plan by participants	A new cycle of mating with Awassi rams started on October 1 with the 2 new rams in the nucleus and 3 high Awassi graded rams from the nucleus in the flocks of the farmers.

Results from the farm Kenesh:

In the mating season 2007 33 crossbred (50% Awassi x LCW) ewes were mated with Awassi sires at farm Kenesh for obtaining 75% Awassi x LCW lambs. In spring 2008 23 lambs were born (Table 24) 26 local coarse wool ewes were mated with the same Awassi sires and 20 lambs (50% Awassi x LCW) were born. No difference in liveweights between 50% and 75% Awassi lambs were observed (Table 26).

Table 26. Liveweights of Awassi crossbred lambs born in 2008

Genotype	Sex	n	Live weight, kg	
			At lambing	At 1 month
50% Awassi	female	9	3.8 ± 0.04	9.9 ± 0.06
	male	11	4.1 ± 0.03	10.3 ± 0.10
75% Awassi	female	12	3.7 ± 0.04	9.8 ± 0.09
	male	11	4.0 ± 0.02	10.2 ± 0.11

Results in Progress village:

Four households in Progress village (Chuy region) started using Awassi rams in the mating season 2007 with support from Kenesh farm (Nurjan Abdymajitov). In total the four participating households obtained 55 crossbred (50% Awassi x LCW) lambs, of which 29 were female and 26 male (Table 27). The liveweights of the crossbred lambs in the households were slightly lower than at Kenesh farm.

Table 27. Liveweights of F1 crossbred lambs in four households in Progress village,

Name of household	Sex	n	Live weight (kg)	
			At lambing	At 1 month
B.Ashirov	Female	6	3.3	9.3
	Male	4	3.6	9.6
T.Esenaliev	Female	7	3.2	9.2
	Male	8	3.6	9.6
A.Tashbolotov	Female	8	3.2	9.2
	Male	7	3.5	9.5
A.Esenaliev	Female	8	3.2	9.2
	Male	7	3.6	9.6

Mating season 2008:

The activities to be conducted during the breeding season 2008/2009 were jointly planned with the framers and scientists during the visit of Joaquin Mueller in November 2008.

At Kenesh farm mating of 80 ewes was conducted from 1-31 October 2008. The two sires (no. 1058, 1983) bought in Kazakhstan in 2007 were used for mating. The new breeding cycle in Progress community also started in October 2008 with mating ewes in the four flocks with crossbred Awassi sires from Kenesh farm (Table 28).

Table 28: Mating in Progress village in October 2008

Household	Ewes mated	Rams used*
Altynbek Esenaliev	15	Crossbred
Azimjan Tashbolotov	15	Crossbred
Bakhtiyar Ashirov	10	Crossbred
Tolobek Esenaliev	15	Crossbred

*Awassi crossbred rams from Kenesh farm (ear tags: 6299p, 6289p, 6234p).

1.3.6 Activity 11: Set the basis for a decentralized and participatory breeding plan for farmers to access improved animals

Location: Kemin district – households in “Akbeke” village

Activities and results:

The design and implementation of a breeding plan for a group of farmers in Akbeke with the aim to increase sheep meat production started in October 2007. Originally all 10 households participating in Activity 9 were interested in the breeding scheme. But after farmers considered the risks involved by using a new breed and realizing the work involved, some declined to participate and others were excluded due to insufficient quality of their ewes. There are now 5 farmers actively involved in the breeding plan (Table 29).

Table 29. Mating in November 2007 in Akbeke village

Farmer	Ewes mated (numbers by April 2008)	Id of ram used
Aman Omonov	18	4131
Erkin Toktogonov	21	4124
Joldosh Mambetaliev	6	6726
Keldibek Toktogonov	23	4144
Shaken Rysbekov	19	6726
Total	87	

Table 30 shows the working plan originally agreed on and the corresponding performed activities during the first year of implementation 2007/2008.

Table 30: Planned and performed activities in Akbeket breeding scheme (composed by Mueller in November 2008)

Date	Planned Activity	Performed Activity
Oct 2007	<u>Sire selection:</u> Participants travel to Aikol and select foundation sires. Note: if there is a good sire in the community he could be used together with the Aikol sires allowing a comparison of the progeny from local and Aikol genotypes.	Two participants (Shaken Rysbekov and veterinarian Joldosh Mambetaliev) traveled with scientists to the Aikol farm in the Tonsk district and selected 4 foundation rams.
Oct 2007	<u>Ewe classing:</u> Upon return of ewes from summer grazing good ewes are identified and ear-tagged. Inferior ewes are culled if replacements are sufficient. Ewe classing will be based on criteria discussed between participants and technical team (an example of such criteria is given in Table 1 of an attached Excel spreadsheet).	A total of 87 ewes of 5 households were selected visually and on body weight for mating the Aikol rams. Some details of the classing were recorded. See Akbeket 2008 spreadsheet.
Nov 2007	<u>Mating:</u> All ewes are pen-mated to Aikol sires giving priority to best ewes. Sire-ewe mates and corresponding mating dates are recorded (Table 2) to enable pedigree recording of progeny.	Mating started 17 November in individual household groups. There were 4 mating groups since the ewes of Joldosh Mambetaliev joined the ewes of Shaken Rysbekov for mating. The recording of mating dates was conducted by one of the farmers, Joldosh Mambetaliev, with visits by Kuban Abdykerimov to the farms.
Apr 2008	<u>Lambing:</u> Birth date, birth type and birth weight is recorded and lambs are ear-tagged (Table 3).	Done. See Akbeket 2008 spreadsheet.
May 2008	<u>Marking:</u> At marking all lambs are weighed (Table 4) and weights are analyzed (Table 5). About 20 male lambs with high growth rate born from superior ewes are not castrated and are candidates for future sire replacement. Decisions are made here on the basis of the data results.	All lambs were weighted at about one month of age. All lambs were retained. Inferior males will be castrated later.
May 2008	All animals go to summer pastures.	Done.
Aug 2008	<u>Weaning:</u> Weaning takes place in summer pastures. Weaning weights of ear-tagged lambs are taken (Table 4).	Effective separation of lambs from dams is not possible on summer pastures and lambs progressively wean naturally. Weaning weights were not taken.
Oct 2008	All animals return from summer pastures and ear-tagged lambs are weighed (Table 4).	All animals returned from summer pastures earlier than planned, on September 10, due to the intense drought. On September 28 all lambs were weighted.
Oct 2008	Weights are analyzed and about 10 male lambs are selected on growth rate and visual quality for final performance testing (as in Table 5).	All lambs were kept.
Oct 2008	<u>Performance testing:</u> Selected male lambs are managed together during the winter in a single flock (will get their final weight in May 2009).	Lambs were managed in respective households.
Oct 2008	<u>Ewe selection:</u> Select young replacement females and re-class adult ewes (Table 1	All young females were retained due to the small number available and the intention to

Date	Planned Activity	Performed Activity
	and 6). Put ear-tags on new ewes (using new numbers). Young replacement females will be selected and adult ewes will be reclassified. The first 2 years this will be done on the basis of the ewes' own performance.	increase flock sizes.
Oct 2008	<u>Sire selection</u> : After one year, the adaptation of Aikol rams to the Akbeket production condition and the performance of their progeny can be assessed. Results of this assessment may indicate the necessity of the replacement of one or both sires (Table 7).	One ram died and another got lame. These two rams were replaced with two new rams (Numbers: 5890 and 5894). All rams performed very well in terms of quality of the progeny produced.

As can be seen in Table 30 the work done in the first year of implementation has been in acceptable correspondence to the original plan. Specific changes are being discussed in detail in Mueller's report. From the 87 ewes mated in November 2007 82 lambs were obtained (Table 31) that were ear-tagged and weighed at lambing and in monthly intervals till 6 month of age. Data are being analyzed and will be fully reported in the final technical report.

Table 31. Average liveweight (kg) of lambs obtained from Aikol rams

Sex	n	At lambing	At 1 month
Female	49	3.3 ± 0.02	9.3 ± 0.02
Male	33	3.5 ± 0.02	9.6 ± 0.03

The Akbeket plan has started well, despite the very cold winter 2007/2008 and the very dry summer 2008. The second mating season for the ewes kept by the five Akbeket community members was conducted from 1-30 October 2008. 81 of ewes were mated with 4 sires (5890, 5902, 5894 and 5901).

1.3.7 Activity 12: Community-based household cow and sheep milk processing improvement for value addition and income increasing

Location: Kemin district – Alimseyit" farm and households in "Akbeket" village

Models of mini dairy plants for processing of 1000 and 2000 kg milk daily made in the Russian Federation were discussed with farmers. However, the price of these mini-plants is quite high and not affordable for the farmers.

Since the initiation of the project this activity has not will not be continued in 2009.

Tajikistan, Sogd province, Khujand site

1.3.8 Activity 13: Improvement of goat breeding in households for improved productivity (flock structure, feeding, selection/culling and animal health)

Location: Sogd province – villages Koradjingil, Takli, Uyas

Objective:

The main objective is to test a number of low-cost husbandry practices to improve flock productivity and farmers' incomes.

Activities and results:

Table 32 gives an overview of the husbandry practices that were implemented in the “improved” flocks compared to the common practice in the “traditional” flocks. Originally 13 traditional flocks were selected, but data collection became very demanding. Thus the number was reduced to only 7 control flocks (see Table 34) with good information (about the same number as “improved” flocks).

Table 32. Comparison between improved and traditional farmers

<u>Experimental group:</u>	<u>Traditional (control) group:</u>
Recording of changes in the flocks according to age and sex groups introduced (Flock rotation form)	No records taken
Optimization of flock structure	Optimization of flock structure not done
Recording of flock productivity	Recording of flock productivity: some owners record total sheared fiber yields
- Number of kids born and their weighs (at kidding, 1, 2, 6 month age);	
- kids survival rate till weaning;	
- Sheared fiber yield	
Individual record keeping for nucleus animals and tattooing	Animal identification and Individual record keeping not common, was only used in state farms
Evaluation of fiber quality in spring	Evaluation of fiber quality not done
Evaluation and classification of all animals in the flocks and determining their purpose in autumn (pedigree, production and culling)	Classifying and culling animals is not done in a systematic way
Strategic and balanced feeding (taking into account requirements and available feeds)	Additional feeding in the winter period is only done in very harsh weather conditions without taking into account physiological condition of the animals
Well planned veterinary intervention with regard to prevention of infectious diseases and parasites	Veterinary treatments are only conducted in case of disease

Implementing of recording of flock changes

For this purpose a simple recording format was developed and distributed in a booklet to the participating farmers. The main aim is to train farmers in recording and assessing their flock structure as a first step towards optimizing the structure with regard to increasing the proportion of productive animals. The flock structure in the experimental group has already improved in comparison with the traditional group (Table 33). In the flocks of the improved group on average one buck is being used for 26 does. In most flocks of the traditional group there is a surplus of bucks with an average relation of does to bucks of 7.3 to 1 meaning that the number of bucks is about 4 times higher than required (Table 34). The exception is one farmer that does not keep any buck. Thus, the proportion of does in the flock has increased by 6.8% and the share of bucks decreased by 3.5% compared to the traditional group.

Table 33. Flock structure in the improved group

#	Farmer's name	Total	Reproductive part			
			does		bucks	
		heads	heads	%	heads	%
1	Turgunboy Madaliev	146	90	61.6	4	2.7
2	Rahmon Askarov	121	52	42.9	2	1.6
3	Abdunazar Matazimov	314	120	38.2	3	1.0
4	Sherali Tilloev	94	50	53.1	2	2.1
5	Sulaymon Umarov	146	53	36.3	3	2.1
	Total	821	365	44.5	14	1.7

Table 34. Flock structure in the traditional group

#	Farmer's name	Total	Reproductive animals			
			does		bucks	
		heads	heads	%	heads	%
1	Abduvohid Mamtkulov	132	48	36.4	8	6.0
2	Abdurahmon Hayitmatov	42	19	45.2	3	7.1
3	Abdumalik Khanaev	70	23	32.8	4	5.7
4	Komil Mamatkulov	32	15	46.9	1	3.1
5	Ravshan Dushaboev	64	23	35.9	0	0
6	Abdulahob Uskanov	53	19	35.8	5	9.4
7	Boir Parpiev	41	17	41.4	2	4.8
	Total	434	164	37.7	23	5.2

Measuring productivity and classifying individual animals

The criteria developed for classifying individual ewes were explained in the last progress report. Special attention was given to the selection of replacement animals with a good size (at the age of 1.5 and 2.5 years). The best goats were tattooed with individual numbers and designated for the nucleus flock (activity 15). Animals to be culled were designated for selling and/or fattening for slaughter.

A booklet entitled "Individual classification of does and bucks (fiber length, fineness, density, sheared fiber yield, animal's age and size)" was translated into local language and distributed to each farmer of the improved group.

In spring 2008 individual classification of animals was conducted in the improved flock and the results compared with the traditional flock (Table 35). The table shows that the animals in the two groups differ in the evaluated characteristics. Liveweight of bucks in the improved group was by 11.7% higher than in the control group. For does this difference was 6.4%. Fiber length of the animals in the improved group was greater than for animals of the same age in the control group. Fiber fineness of the goats of control group was less uniform than in the improved group. The highest fiber yield per head (2.95 kg) was obtained from bucks in the improved group, which exceeded the yield in the control group by 40.5%. Average sheared fiber yield from does in the improved group was 1.55 kg and 17.4% higher than in control group. The superiority of the improved group over the control can be possibly explained through the introduction of selection strategies and additional feeding (concentrates and mineral) but the flocks might have already differed at the start of the project.

Table 35. Results from individual classification of the adult goats

Groups	Sex	Obtained progeny head (%)	No of lambs at 6 month (%)	Animals' evaluation				
				Live weight (autumn)	Natural fiber length (cm)	Fine-ness (Bradf.)	Fiber yield, kg	
							total	per head
Experimental	Bucks	-	-	52.2	21.5	48-46	71	2.95
	Does	284 (72)	272 (96)	29.8	18.2	56-48	820	1.55
Control (traditional)	Bucks	-	-	44.5	19.0	56-48	65	2.10
	Does	90 (55)	81(90)	28.1	17.5	58-48	363	1.32
Difference (exp - control)	Bucks	-	-	+7.7	+2.5	-	+5.8	+0.85
	Does	194 (17)	191 (6)	+1.7	+0.7	-	+457	+0.23

Improved feeding with taking into account goats' requirements and local availability of feeds

The last winter was the longest and coldest for the last 40 years. Animals could not to graze on pastures. The project supported additional feeding of pregnant and lactating does in the six improved farms with oat grains (100 g per day to each animal for one month).

The project also proposed supplementation with minerals from local sources, namely bentonite clays. Basic components of bentonite clays are silicon (19.6%), aluminum (5.4%), calcium (10.4%), magnesium (3.0%), gland (1.2%) and phosphorus (0.5%), and others in the range from 0.001 to 0.1%. The mineral supplement is offered in the form of briquettes, composed of bentonite, bone flour, chalk, copper sulfate, iodide potassium, and common salt.

Disease prevention program

ХУДЖАНД - 2008

In the improved flocks all preventive measures were done as planned in the reporting period. The brochure “Brief Farmer’s Handbook” was developed and distributed. This handbook describes the main goat diseases in the region and prophylaxis and treatment. The book includes a calendar showing the disease prevention measures to be taken in the different seasons of the year.

1.3.9 Activity 14: Improvement of shearing and classification of fiber, standardization, based on the international standards, by quality, impurity and age

Location: Sogd province : villages Koradjingil, Takli, Uyas

Objective:

The objective of this activity is to improve market prices achieved for Mohair fiber through assortment during shearing into different quality classes at least by age and sex, and to develop a new standard for Tajik mohair.

Activities and Results:

The following activities were conducted:

- collection of samples for laboratory analysis in Almaty and at INTA;
- conducting of training with farmers and scientists on international qualities standards;
- developing recommendations on requirement of mohair quality for breeding of Tajik mohair goat breed;
- developing draft of new standard for mohair with taking into account international norms.

Collection of fiber samples for laboratory analysis

In spring 2008, 740 fiber samples were collected and split into two parts for testing in Almaty (Kazakhstan) and to draw a random subsample to be tested in the INTA laboratory in Argentina. The samples were collected from different age and sex groups of animals (Tables 36 and 37).

Table 36. Number of samples that were analyzed in Almaty lab

	2007			2008			
	Total	White	Colored	Total	White	Colored	Autumn
Number	68	59	9	740	509	162	69

Total		509		162		69	740

The results from the laboratory analysis in Almaty show that fiber fineness is clearly decreasing with age in both white and colored goats, while fiber length does not show a homogenous trend in relation to age (Tables 37 and 38). Colored goats have slightly shorter fibers than white ones. The fiber from males is coarser than from females. These results indicate that grading by age and sex can be useful to achieve higher market prices for Angora fiber by dividing to classes conducted fiber investigations in Almaty lab.

Table 38. Results of fiber analysis from white Angora goat by age and sex (Almaty lab)

Age group	Sex	Fineness (µm)	SD (%)	CV (%)	CF – comfort factor (%)	Average crimp	Average length (mm)
Yearling	♀	26.4	7.48	28.4	73.3	15.97	186.3

Conducting of training with farmers and scientists on classing fiber by age and sex.

A training was conducted on 3 May 2008 in Uyas village:

Trainer: M. Kosimov, Assistants: R. Mamatkulov, F. Kosimov.

Participants: Abduvokhid Mamatkulov, Sulaymon Umarov, Abdufattoh Khonaev, Sherali Tilloev, Turgunboy Madaliev, Mardonkul Imomkulov, Hudoiberdi Kholmirezov, Abdumalik Khanaev, Komil Mamatkulov, Ravshan Dushaboev, Boir Parpiev

The training consisted of a theoretical and practical part. The theoretical part included:

- Importance of fiber fineness of Angora mohair.
- Relation of fiber fineness with age and sex of goat
- Other factors affecting fiber's fineness (feeding, maintenance and individual features).

The practical part included demonstration and presentation of fleeces, and examples of fibers from different age and sex groups (at house A. Mamatkulov).

Developing a new standard for mohair taking into account international norms

The current classification system of Mohair in Tajikistan does not meet international market requirements in particular for fiber fineness. The results from the laboratory analysis of the fiber will help to develop a new standard in line with international standards.

1.3.10 Activity 15: Set the basis for a decentralized and participatory breeding plan for farmers to access improved animals

Location: Sogd province, Karajingil, Takli and Uyas villages

Objective:

The goal of the activities is to create a decentralized community based breeding scheme to facilitate access of farmers to improved animals.

Activities and Results:

The followings activities were undertaken to reach this goal:

- Formation of breeding flocks with the best goats in the target and neighboring villages
- Development of breeding plans with the communities informed by market assessments
- Implementation and Farmers' training on selection schemes and establishment of simple recording systems

Participants in the breeding programs

At the planning stage in September 2007, eight farmers were identified as willing to participate in the development of an Angora breeding plan. However in the process of discussing details of the work, two farmers finally refused to participate. These farmers were replaced with two new farmers. In addition another farmer may be included in 2008. From the five active farmers two may not continue since they are facing different kinds of problems. It looks as if the final number of participants will be 5 or 6, which given the farm access difficulties and distances, is a reasonable number to work with. Table 40 summarizes the list of farmers with their present involvement in the breeding plan.

Table 40: List of farmers and present involvement in breeding plan

Farmer	Details
Abdufattoh Khonaev	Abandoned. First he was afraid of animal identification, and in autumn 2008 he decided to sell his animals.
Abdumalik Khoji	Abandoned early
Abdunazar Matazimov	Active nucleus
Anarbai Kosimov	New nucleus
Mamarasulov Suyunboi	New black nucleus
Mamat Isomiddinov	New nucleus
Rahmon Ascarov	Nucleus, had many losses and moves a lot

Sherali Tilloev	Nucleus, coarse goats and not very interested colored
Sulaimon Umarov	Active nucleus
Turgunboi Madaliev	Active nucleus

Breeding structure

In terms of the breeding plan the five active participants are not an integrated group as such, since there are no breeding links between the flocks of the farms. Rather each farm has its own breeding plan based on a number of animals identified as nucleus animals. In addition each farm has its own bucks. This means that only the genetic variability within flocks is exploited and not the variability between flocks. Bucks which could be improvers in one farm but were born in another are not accessed.

In the actively participating farms all animals, nucleus and base, are kept together during mating, only one farmer (Sulaimon Umarov) separates nucleus and base allowing mating of the best with the best as proposed. Another farmer (Turgunboi Madaliev) mates nucleus females with best bucks during peak of oestrus joining all animals afterwards, therefore increasing the probability of having nucleus females mated to best males. Other farmers mate the whole flock only with selected bucks. This procedure means that only part of the potential selection intensity is used.

Breeding for color

Another important point is that from what could be seen, white and colored animals are run together, even during mating. All five flocks have mixed color flocks. This is actually not bad as there is a market for fleeces of different uniform solid color in the cottage industry (Brent 2008). However if mating across colors is allowed, non-solid color and non-uniform fleeces are produced. Mohair from such fleeces is difficult to process in high quality yarn and fabrics and is discarded by the industrial processors. In addition cross-color females maintained in the flock produce more variable offspring due to segregation.

Therefore it is suggested to use only solid color bucks in one mating flock, that is typically white or black. If complete separation is not possible farmers should try to separate colors at least during the peak of oestrus (eight days or so). This separation is of course even more important for nucleus females. If this is also not possible the option is to work on obtained progeny by culling non-solid colored animals. This needs reproduction to be high and for this to happen management must be optimum. Success of activity 13 (goat management) is therefore crucial in this aspect.

Breeding objective

Within a color, the original breeding objective for all farms was to improve fleece weights and to improve mohair quality without losing body weight and fitness. Improvement of Mohair quality refers to increasing staple length, reducing contamination (medullated fibers and kemp) and improving style, character and luster.

It is clear that breeding objective changes will be driven by market signals, in particular Activity 16 is showing that fine Mohair is far more profitable than the present strong Mohair (see report of Dr Liba Brent). Farmer convincement to breed for finer Mohair will need various inputs: tangible market opportunities, farmer's women intervention, future market outlook information, objective data from the technical team, etc.

At present the variability in fiber diameter between fleeces is apparently very high (objective information is being processed) and very fine, kemp-free fleeces are available amongst kid fleeces, particularly if shorn early. Fiber contamination with kemp is another issue not considered in traditional selection practices. Kemp is a problem at all fiber diameter categories and only of interest in some carpet products. High value Mohair should be free of kemp. This breeding objective has been more easily accepted by farmers. However improvement will take time since the amount of kemp observed is quite high in most animals.

Selection

Last year a detailed account on selection procedures was given, including visual selection criteria, measurements and final decision criteria. The actual use of these procedures is not clear and probably taken only partially. For example only very few progeny was left from the nucleus does in November 2008 (see Table 41). From the 116 nucleus does only 53 kids are available. There are several reasons for this low figure including bad climatic conditions (cold winter and dry summer 2008) which limited reproduction and survival but also heavy culling has taken place before performance data became available. First shearing will be in April 2009 and selection pressure on measured performance will be very low.

This point has been discussed and needs further discussion. If selection takes place without consideration of objective performance then there is no point in measurement and fleece sampling. Genetic progress will be slower than actually possible (about 50% slower). Use of preset selection criteria (measurements and visual) is useful for systematic selection, analysis of progress and for uniform extension work.

Recording and performance

Individual identification of goats is not common among private goat owners. In the past only the goats on state farms were ear-tagged or tattooed and there were cases when animals with individual numbers were confiscated. As there are still many state goats, it was difficult to convince farmers to agree in tattooing their animals (see last progress report). However, now all nucleus animals in the active nucleus flocks have been tattooed. A. Khanaev was excluded from the list of participating farmers because he refused to tattoo his goats and later he sold his animals.

Field records were taken from all five farms. Field records included body weight in autumn, fleece weight, staple length (measured with a ruler) and visual fiber fineness (on the English Bradford scale) in April. In addition fleece samples were taken from all animals and sent to the Alrun Wool Laboratory in Almaty, Kazakhstan for analyses. Averages for nucleus does and bucks by farm and color are shown in Tables 41 and 42.

Table 41: No of animals in November 2008 and average field records for nucleus does per farmer

Farmer	Goats		Nucleus		Color	Nucleus progeny		Nucleus does

Veritable fiber length (cm)	178.6	173.5	190.2	-	197.3

In spring 2008 the kids born were recorded and tattooed (adding the number 8 for the birth year). Some of the mated does did not conceive and some aborted due to the very severe winter resulting in a relatively low fertility that also differed between the farmers (Table 43). Liveweight gains of the kids in the nucleus flocks did not differ much between farms and daily gains in the first 180 days were quite low due to the dry summer (Table 44). However, in this period the daily weight gain in the nucleus flock was slightly higher (72 g) than in the control flocks (66 g, Table 44).

Table 43. Reproductive performance of does and kid survival

Parameters	Turgunboy Madaliev	Sulaymon Umarov	Rahmon Askarov	Abdunazar Matazimov	Sherali Tilloev

Mating in October 2008

Mating started in October and kidding is expected for March-April 2009. Promising male kids born from nucleus does (visually superior and born from best females) will be kept un-castrated. These males and the female kids will be ear tagged or tattooed. In fact as many male kids as possible will be kept un-castrated in order to increase selection pressure.

During mating period best does were grazed with the best bucks. All mated pairs were recorded for further using these records in genotype identification.

1.3.11 Activity 16: Value added local processing of goat fibers by women and assessing the characteristics of naturally colored mohair and the potentials for its marketing

Location: Sogd region, villages: "Katabulak", "Adrasman", "Takli", "Karadzhangil" and "Taboshar"

This activity is implemented under the guidance of Dr. Liba Brent (University of Madison, Wisconsin) and was carried out as planned. A detailed updated report was prepared by Liba Brent in March 2009 and shared with IFAD.

Objective:

The main objective is to develop market opportunities for value added fiber products, in particular naturally colored mohair and silk yarns, dyed white mohair and silk yarns and knitted handicrafts.

Activities and Results:

Most rural women in Tajikistan make a living by producing coarse, cheap yarns for the Russian market. Given the substantial differences between the price of handspun mohair yarns on the Russian and the American market, the Tajik spinners have a strong economic incentive to produce yarns for export to the US. The ICARDA project is helping the women to access the US luxury market with fine yarns through capacity building in the following activities:

- 1) Working with women's groups on improving spinning technique to produce fine, even yarns.
- 2) Introducing new technologies such as spinning wheels to improve productivity and the ease of spinning.
- 3) Producing yarns samples for the US market, bringing in market feedback and test-marketing yarns.
- 4) Organizing women's groups into cooperatives that can effectively perform all tasks including yarn spinning, packaging, marketing and quality control.
- 5) Training women to produce knitted luxury products (shawls, sweaters) for export.
- 6) Training women in fiber selection and linking women's groups with Angora goat farmers who produce quality mohair.

1) Working on yarn production: training spinners to make fine yarns.

During the first two years, the project has trained six groups of spinners (overall 45 women) in spinning luxury yarns. In November 2008 the project began collaborating with 12 additional organized women's groups (with 6-12 women in each group) and training them to spin fine yarns. The women were shown samples of Australian, South African, French and Italian yarns currently on the US market and explained how to produce yarns according to the standard established by the project. Based on the project experience, the majority of women who have enough experience in spinning yarns for the Russian market can be relatively easily trained to improve quality and produce fine yarns for US market. In the next phase of the project, training will be facilitated by training trainers and publishing a spinning manual that explains the quality standard for the US yarn and includes a small yarn sample.

The interest on the part of the women to join the project and learn how to produce fine, high-priced yarns has been considerable and it is clear that hundreds of women from the region could successfully participate in producing quality yarns for the US and other luxury markets in the future. Provided that they had access to quality kid mohair, it is most likely that all spinners capable of producing fine yarns according to the project standard would switch to this market while those who cannot meet the standard or are still learning how to spin would continue to make yarns for Russia. The project will work on producing more specific estimates of potential beneficiaries in the next report in spring 2009.

2) Introducing spinning wheels: increasing productivity.

The project has imported four New Zealand spinning wheels and distributed them among the women. Based on their testimonies, the use of a spinning wheel increases the spinner's productivity at least by 50%. The spinning wheels are also much easier to use than the traditional spindles and the women learn how to use them relatively quickly. Most women expressed a desire to obtain a spinning wheel and the project is trying to facilitate a domestic production of spinning wheels - the imported spinning wheels cost \$400/piece and domestic production is the only viable long-term option. Several masters in Tajikistan began producing prototypes of spinning wheels based on the imported models but additional investment will be needed to fully develop the production.

3) Producing yarn samples, receiving feedback and test-marketing yarns.

Since the start of the project, the project coordinator based in the US has maintained a relationship with American knitters and yarn storeowners who have been testing yarn samples produced by the spinners. The individual samples have been registered and the spinners received a direct feedback from the knitters. After two years of sample testing, the project has developed a standard for the yarns to be exported and new spinners are being trained to maintain the standard. New types of yarns will be developed in the course of the project and standardized, including silk/mohair blends spun from locally produced fibers and yarns dyed with natural and chemical dyes.

The US market for knitting yarns has been in the process of considerable boom. Based on the research conducted by the project, the retail prices of some luxury kid mohair yarns were as high as \$560/kg. The market for knitting yarns in the United States provides a perfect opportunity for the Tajik women – it values yarns made from natural fibers such as mohair and prefers handspun yarns over machine-spun yarns. The prices of fine, kid mohair yarns are much higher than \$10/kg the Tajik women receive for coarse mohair yarns made for the Russian market. In addition to knitting yarns, the US market presents an opportunity for the sales of luxury items such as scarves, sweaters and other knitted products.

In order to promote the Tajik mohair yarn in the US, it is important to inform the American knitters and consumers about the project, the Tajik women and the qualities of the yarn and products. The project developed a website that explains the project objectives, describes the yarn and offers photographs and information about the spinners. A brand name “Mohair Magic” has been established and a booklet was designed that accompanies the yarns marketed in American stores. A variety of other means will be used to increase information and public awareness about the project activities. The US knitters are starting to work to publish an article about the yarn in the Spin Off Magazine and the Vogue Knitting Magazine expressed interest in publishing an article about the project.

In February 2009, the first 18 bundles of mohair yarns are being test-marketed in the Sow’s Ear store in Verona, Wisconsin, USA. The yarns will sell for a price of comparable kid mohair yarns produced by the Australian Company “Wagtail Yarns” for a wholesale price of \$140/kg. The women will receive \$70/kg and \$70 will be used to export the yarns from the community in Tajikistan to the US yarn store.

Given that most of the shipping and other costs are currently subsidized by the project, all proceeds from yarn sales will be re-invested into the project activities through a “Magic Mohair Fund.” The fund will be used by the project to purchase raw material for the spinners and benefit the producer’s communities in ways that will be agreed upon jointly with the project team. The possible options include purchasing raw fiber or spinning wheels for the women and designing micro-lending schemes.

4) Organizing women’s producer cooperatives.

The project plans to collaborate with a local NGO “Agency for the Support of Development Processes NAU” to organize the spinners’ groups into cooperatives that will be responsible for yarn production and export. The NGO established 12 cooperatives in the Asht region that are focused on producing yarn for the Russian market. These cooperatives include 6-12 women members, are lead by elected women leaders and are starting to use micro-lending to purchase raw mohair for spinning. The project plans to collaborate with the NGO on further developing the cooperative infrastructure with the orientation on the American market.

In November 2008, the project team visited several of the cooperatives and explained the project activities and objectives to their members. In the spring of 2009 the project plans to include the groups in the training.

5) Training women to knit clothing.

In October-November 2008 the project began collaborating with knitters in Tajikistan to use some of the yarn to knit shawls and sweaters based on western models. This would add more value to mohair and open a new market for knitted clothing. However, currently there are only a few experienced knitters in Tajikistan who have the skills to produce such products – most women are able to knit only socks, gloves and in some cases simple scarves. The project plans to expand the search for knitters in 2009 and begin the training of trainers to develop this new component. In spite of the current limitations, knitting is another viable opportunity to add additional value to local fiber, introduce new skills and create new earning opportunities for women to supply products to luxury markets.

In November 2008, the project team started working with two knitters in the city of Khodzhand who produced a sample of a scarf and a sweater based on a US model. Both samples received high marks from US knitters and potential buyers. The project plans to continue working with the knitters in the spring of 2009, add new knitters to the group and start developing a training program for knitting luxury scarves, sweaters and other items for the US market.

6) Training in Fiber Selection and Linking Spinners with Mohair Producers.

The most important factor that influences yarn and product quality is the quality of the fleece from which it was spun. Even the most skillful spinner cannot produce fine yarn unless she has high quality raw mohair. Unfortunately spinners have been using low quality mohair to spin yarn for the Russian market and do not know how to correctly select fleeces to produce fine yarns for the US market. The project has been training all groups in fiber selection and in sorting and grading individual fleeces. Given that the spinners have considerable incentives to produce fine yarn for export, the groups that received training have been very proactive in searching for quality fiber. However, their search for fine, kemp-free mohair has been challenging because of the poor breeding practices of local farmers.

Based on the project research, the quality of fleeces produced by different farmers varies considerably. A minority of farmers produce Angoras with finer mohair that have less kemp and the project can use as many as 80% of their kid and yearling fleeces, and about 30% of skirted fleeces of older goats, for yarn-making. However, the majority of farmers produce animals with coarse fiber that has a high percentage of kemp and cannot be used for spinning luxury yarns. In some cases, none of the goats a farmer produces, including 6 months old kids, have fiber that is fine enough for luxury yarn. The project plans to assist the spinners by linking them with farmers who produce finer mohair and work with those farmers on further improving fiber quality. Therefore, Angora breeding program is perhaps the most important component of the project – the yarn spinning and marketing activities cannot be scaled up unless the Angora goat farmers can supply the spinners with quality raw material. In order to facilitate this, the project needs to identify farmers who currently produce the highest quality fiber, link them with groups of spinners, and work with them on further improvements in breeding and fiber quality. The selected farmers need to receive technical, scientific and organizational support to develop breeding nuclei that will have the capacity to produce breeding animals for farms in the region.

If breeding is improved, Tajik farmers can fully capitalize on some of the unique qualities of Tajik Angora goats and the mohair they produce. Although most Tajik Angora fleeces have a serious shortcoming in terms of the presence of kemp fibers, they also have an advantage over Australian and American Angora kid fleeces by having a higher percentage of fine, cashmere-type fibers that make the Tajik mohair yarns softer than Australian or American yarns. Softness is perhaps the most important criteria by which knitters judge yarns. Soft yarns can be made into soft shawls, and sweaters that appeal to the final users. The presence of cashmere fibers (especially if they are longer) also makes the Tajik mohair more “spinnable” and less slippery. This is also an advantage during manual processing. The project plans to continue to research the comparative qualities of Tajik mohair and study how different types of fleeces affect yarn quality. The research results will be used to develop breeding strategies and programs. Farmers will be encouraged to form so-called “spinners’ herds” – flocks of fine-haired goats that will be sheared specifically for spinning.

The finest and most valuable mohair is so-called “super-kid” mohair produced by 6 months old Angora goat kids. However, prior to the project activities, there has been no demand for this type of fiber on the Tajik market. Some farmers sheared 6 months old kids for other reasons – in some areas small kids can get caught on spiky plants and die and farmers shear them to prevent this. The project started working with farmers to shear 6 months old kids for super kid mohair and working with spinners to produce super-kid mohair yarns. Based on the first results of the test-marketing, these yarns will be most desirable by the knitters. Six month old kids also have the least amount of kemp and using their fiber will help to resolve the fiber quality issues experienced thus far.

Tajikistan – Dushanbe site

1.3.12 Activity 17: Improving sheep management in the communities, aspects of feeding, lamb breeding, maintaining and sheep reproduction

Location: Buzbit, Nematobod, and Karsang (Dusti jamoat), Vakhdad district.

Objective:

The objective of this activity is to test improvements in management strategies that can be easily adopted by farms and households.

As planned two subactivities were conducted in 2008:

- additional feeding of ewes during gestation period and studying ewes reproductive abilities, lambs growth and development;
- early weaning of lambs (at 3 months) and their subsequent growing, studying growth and development of lambs and productivity of their mothers;

Sub activity 1. Additional feeding of ewes during gestation period

Two groups of 30 ewes each were formed in February 2008 from the flocks of two farms (A. Bobokhonov and K. Ne’matov) that graze their sheep on winter pastures (at the boundary Kyzyl-Aryktov). Pregnant ewes of the experimental group (farmer A. Bobokhonov) were supplemented with 0.3-0.4 kg of concentrates during the last third of the gestation period. The concentrates consisted of a

The trainers have been focusing their efforts on improving women's knowledge of safe collection, handling and processing of milk. The main bottleneck to generate cash income from this activity is finding sustainable market channels. The products are currently marketed by the husband or a male representative of the family who find it difficult to find customers and achieve good prices.

2.4 Theme 4: Knowledge exchange

Rainfed and irrigated sites

2.4.1 Activity 5: Enhancing knowledge exchange for increased feed and livestock production

Objectives:

- To disseminate fodder production technology among the farmer community
- To motivate the farmers to adopt improved varieties and improved agronomic practices
- To get feed back from the farmer community so that the problems can be solved.

Activities undertaken:

- On the job training of participating farmers in fodder crops production, hay making and feeding at both project sites
- One field/demonstration day organized by the project in Lodhay village was attended by the community members to discuss the interventions
- One formal and one informal training course on improved fodder varieties and production technologies during the reporting period including lectures and discussions were conducted in Lodhay village
- Two formal and about ten informal training courses on livestock feeding and productivity in general were held in Lodhay
- Formal and informal training of farmers and women groups in hygienic milking and value addition (increasing shelf life, dairy processing techniques) at both project sites (see Activity 4)
- Networks of collaboration have been developed at each site with different institutes working on fodder crops, livestock and dairy processing; monthly meetings of the project team are conducted
- Graduate students from socioeconomics, agronomy and dairy technology were involved in the project activities.
- Contacts with private seed companies and the Punjab Seed Corporation were established to improve fodder seed supply.
- The annual progress report was submitted in March 2009

The training courses for scientists (forage evaluation; integrated crop livestock production; experimental design and analysis; and scientific writing, reporting and data presentation) planned for the second half of 2008 were not conducted due to security problems in Pakistan and lack of skilled trainers.

3.3 Activity 3: Capacity building: English training of scientists to improve the international scientific exchange

The activity was conducted as planned and has been described in the Second Annual Progress Report.

3.4 Activity 4: Project supervision and interregional knowledge exchange: regional workshops and SCM

The expected outcomes were:

- SCM to be held in November or December 2008 in one of the participating countries or at ICARDA.
- At least one supervision visit of all PIs in both regions

The regional workshop discussing project results in Central Asia and Pakistan (25 November) and the second SCM on project planning and implementation (26 November) were conducted in Dushanbe/Tajikistan as Islamabad was not considered as safe. On the way to Dushanbe most participants took part in the field day in Khojand on 24 November. On 27 November a second field visit was arranged to the Dushanbe site.

The progress implementation in Central Asia was monitored by frequent visits of POs at strategic times in all three countries. The POs are being supervised and backstopped by ICARDA scientists who also visited the project sites. Aden Aw-Hassan visited Pakistan in April 2008 to develop the plan for socioeconomic evaluation jointly with the Pakistani counterparts. He and Mounir Louhaichi attended the regional workshop and the SCM to discuss project progress with all counterparts. Mounir Louhaichi (rangeland scientist) also visited the rangeland sites in Khojand and Dushanbe after the workshop together with the project coordinator, Aziz Nurbekov and the principal investigator. The project coordinator visited Central Asia and Pakistan three times in 2008. She also presented ICARDA's livestock research in Central Asia at the International Conference "Agricultural Research Competence for Central Asia and the Caucasus – 10 years of CAC Program 1998-2008 on 16 September 2008 in Tashkent.

In addition the IFAD supervision mission, conducted from 13-28 April 2008 in Kyrgyzstan, Tajikistan and Pakistan, has evaluated the achievements of the project and made important recommendations (see IFAD Grant 816 Supervision report by Dr Antonio Rota for further information). The recommendations were used to amend the planned project activities in 2008/2009.

3.5 Activity 5: Web based knowledge exchange (Virtual information Center)

The training of resource persons in the partner institutes in Central Asia was completed during 2008. However, so far the training in Pakistan has not taken place due to the security situation in the second half of 2008. The project webpage (www.icarda.org/cac/livestock.asp) has been considerably improved by Sherzod Kosimov, our web designer in Tashkent office, however, the interactive spirit has not yet been achieved which is also due to the very limited capacity of the partner institutes except the veterinary branch of the Kyrgyz livestock institute. Liba Brent has been working on a special webpage for the activities related to value addition (adventureyarns.com) where she plans to include videos and other information. She has worked with Sherzod on her webpage during her stay at Tashkent in April 2008) to improve and integrate it into the project website.

III Problems during the reporting period and steps taken to remedy these problems

Central Asia

The quality of the annual progress reports has improved considerably due to the close interaction of the Professional Officers based in Tashkent office with our nation collaborators. Nevertheless, there are still delays and complications related to the translation from Russian to English.

Experimental designs are not always followed although they were clearly described in the agreed workplans and discussed in the planning meetings. In particular, the comparison between flocks with improved management and control flocks has not been implemented as planned (Activity 9, 11, 17).

Despite our efforts we have not been successful to integrate young scientists on Theme 2 Range and Forage production into our project activities in Central Asia.

Furthermore extreme weather conditions, such as long extremely cold winter in Tajikistan in 2007/2008, flooding in Akdala village/Kazakhstan in spring 2008 and a dry summer, jeopardized some of the project activities in Theme 2 and 3 (see Second annual progress report).

Pakistan

Sartaj Khan, our project coordinator, left NARC beginning of October 2008 to work as full-time project coordinator for FAO. This left a big gap in overall project coordination and in leading the forage production theme at the rainfed site. Due to the limited project funds, no full-time coordinator can be employed. Fortunately Dr. Ansar from Arid University, the supervisor of the master students involved in our project, has kindly agreed to take over project coordination and to oversee the forage activities till the end of the project.

In the feeding experiments where improved and control feeding was practiced in the same farm, we found that the farmers may have distributed improved feeds among all animals. Nevertheless, the farmers are highly interested in these activities (see activity 1.2), and therefore the experiments will be repeated in 2009 but keeping control and experimental animals on different farms. Often fewer animals as planned in the experimental design were found suitable to be included in the on-farm experiments.

Although a high dairy product quality was achieved through intensive training of two women groups at the irrigated project site, marketing the products remains a challenge and options were thoroughly discussed in the national planning workshop. This was also identified as the main issue to be strengthened during the remaining time of the project in the supervision mission.

IV Progress expected during the following reporting period

Year 2009 is the key period for completion of data collection, analysis and reporting on the project activities. It is expected that most field activities will be completed in fall 2009. The successful completion and quality of reports depends on the continued support and personal engagement of all involved national and international scientists.

Some issues deserve special attention in 2009:

- Ensuring completion of data collection, in particular required data for economic evaluation of interventions, and sound data analysis
- Organization of field days with a range of stakeholders
- Producing training material for successful interventions
- Finalizing webpage and refresh training of responsible "webmasters" at the partner institutes in CA and Pakistan.
- Preparation of technical advisory notes (TANs) of successful interventions and aspects of project implementation.
